

## BEACH IN A PAN

This lesson plan developed by:

## Overview:

How do waves shape beaches? Students construct a beach in a pan and investigate the effects of wind and waves on beach shape. Students investigate and sequence sand grain sizes, create various beach profiles and examine issues associated with coastal development.

## Key Concepts:

Students will be able to:

- Explain how wind and waves transport sediment.
- Identify variables (beach slope, wave size and frequency, angle of waves hitting beach) that influence the shape of a beach.
- Describe pros and cons of building on coastlines.

## Materials:

- Photos of sand samples of a beach transect
- 2 clean paint roller trays
- 4 cups of various sized sediments (fine sand, coarse sand, small gravel, mixture) for making a beach in the paint tray
- Water
- Small wave makers (3"x5" pieces of thin wood)
- Wooden popsicle sticks

## Set-up Prior to Activity:

1. If you live near a beach, collect small sand samples at four intervals along a transect from the waterline to the edge of the beach. Take close-up photographs of each sand sample site and label with a number or letter (students will use these to sequence grain size). Keep
track of the location of each sample in relation to the waterline. Make one set of photos for each student group. (If you don't live near a beach, various-sized sediment can be found at home improvement stores.)
2. Gather the materials for each group to make a sandy beach model. Use different sizes of sand and gravel. Paint trays work well as containers since they already have a slope. (If you do not use a paint tray, you may prop up one end of your pan to form shallow and deep parts.

## Duration:

45 minutes
Physical Activity:
Moderate

## Background:

A beach is a dynamic system. It is a river of moving sand and a place where sediment is constantly being transported and deposited. Sediment is transported and deposited by wind, waves and currents. Beaches are found in places suited to sediment deposition, like calm areas between rock outcroppings, shores sheltered by offshore islands and regions with moderate surf.

A variety of sand grain sizes are usually found on a beach. The finest grains are often found furthest from the water. That's due to wind blowing and transporting fine grains up the beach. When a wave hits the beach, much of the wave energy is lost. The largest sediments drop out first and are deposited higher on the beach. The lighter sediments remain in suspension a bit longer and fall out as the wave recedes. The lightest sediments are carried back out to sea and may eventually settle out beyond the surf line. Therefore the largest particles are often found between the low tide mark and the berm, with smaller particles found either offshore or higher up on the beach.

Beach slope is influenced by the size of sand grains and the waves. Coarser sediments tend to produce a beach with a steeper slope. Conversely, a beach with finer sediments tends to be flatter. The force and size of waves influences the beach composition, too. Stronger waves are able to carry away larger particles when they recede, while calmer areas tend to deposit more sediments on the beach and produce a steeper slope. This means that areas with stronger waves tend to be flatter and areas with calm waves tend to be steeper. Since the strength of waves can vary
seasonally, the slope of a beach may also vary seasonally.
Many beaches share a typical profile, though it will vary seasonally. Dunes, cliffs or seawalls are often the area farthest away from the water. Berms are found closer to the water. This is an area where sediment has accumulated parallel to the shore. It is the farthest place where sand is deposited by waves on the beach. The area between the berm and the low tide mark is the intertidal. This is the active zone of the beach where waves crash during the daily rise and fall of the tides.

The dynamic nature of sand can result in challenges to coastal development. With most of the world's population living on the coast, new homes and businesses are built every year in coastal areas. Millions of dollars each year are invested in protecting structures from the natural process of coastal erosion.

Breakwaters, groins, jetties and sea walls are all physical structures used to protect structures from strong waves and prevent the erosion of sand. Breakwaters, structures in the water parallel to the shore, prevent the longshore current from moving sand so sand may accumulate and need to be dredged to keep harbors functional. Groins, structures extending from the beach perpendicular to the coast, often result in the erosion of sand on the downdrift side. Jetties are similar to groins but are used to stabilize large inlets. (Piers are also perpendicular to shore but are built to access ships and boats.) Seawalls are on shore and built parallel to the beach but deflect wave energy into the sand in front of and next to them, which cause erosion. Beach sand is sometimes imported to fight erosion. But that sand is often from deeper waters so is fine grained and often erodes faster. Building on solid substrate, like a rocky shore, and a reasonable distance away from the water, is a more sustainable method of coastal construction.

## Vocabulary:

- berm: the farthest place sand is deposited by waves on a beach
- groin: a structure perpendicular to and extending from a beach
- profile: a vertical view or cross section of land; may show elevation
- sediment: naturally occurring matter that is deposited by water, wind or glaciers
- transect: a sample area, usually a strip of land along a line, chosen for study

## Activity:

## Part 1: Introduction

1. Share the following question with students: How do waves shape beaches? You may write it up on the whiteboard or have students add it to their science notebook. Give students time to write their initial thoughts down or discuss with a partner.
2. Engage students interest about beaches and sand. Discuss beaches with students. Who has visited a beach before? What is a beach made of? Does a beach look the same all year? Why or why not? Are all beaches the same? What moves the sand? (wind and water)

Part 2: Sand Grain Sizes

## Beach in a Pan ${ }_{\text {(cont) }}$

1. Students predict the location of sand samples from a beach transect. Where does sand come from? Why are there different sizes of sand on a beach? Pass out a set of the sand sample photographs and/or the samples. Have them predict which order the sand grains are in from the waterline to the backshore of the beach. Challenge them to sequence the photographs in the correct order and record their prediction on the Sand Grain Sizes student sheet or in a science notebook. (For younger students, discuss as a class.)
2. Students build a beach in a pan and observe the influence of waves on sand grain sizes. Give student groups a paint roller tray, cup for scooping, wave maker and access to sand and water. Each group will need about four cups of sand to fill up the shallow portion of the paint tray. Encourage students to investigate the different textures, colors and grain sizes of sand before adding water. Next have student groups pour water into their pans until it covers a small section of the sand. Challenge them to make waves of the same size and frequency. How do the waves affect the sand? Have students slowly make waves that sweep up onto the sand until at least half of the sand is washed from the sand pile and extends down the slope toward the deep end of the container.
3. Revist the sand samples to make comparisons. Look at the original pictures of the beach transect sand samples. Based on their experimentation, do students want to make any changes in the order they placed the photos? Compare their responses to the expected answers and discuss the forces at play on a beach. How does the size and frequency of waves affect the distribution of sediment? What about wind?

## Part 3: Investigate Forces on a Beach

1. Students investigate the effect of various forces on a beach profile. Have students reshape their beaches. Challenge them to choose a variable (beach slope, wave size and frequency, angles that the waves hit the beach) with which to experiment. How do they think each variable affects beach formation? Pass out Beach in a Pan Investigation sheets or have students record their observations in a science notebook. Have students compare their beach profiles. What similarities and differences do they notice?
2. What did students find out about forces that shape a beach. Discuss some of the similarities and differences between various profiles. Why were there so many variations? What are factors that affect the formation of different beaches? How do you think beaches change over time or between seasons? Brainstorm other variables that may occur at a beach (e.g., wind, a river mouth, and so on.). Can students simulate those variables in an investigation?

## Part 4: Coastal Development

1. Pass out a variety of photographs of coastlines. What do students notice about those that are developed and that have buildings? What do they notice about natural coastlines? Why would people want to build near a sandy beach area? What coastlines would be the most stable for construction? What are some ways people may combat beach erosion near developed coastlines?
2. Challenge students to develop, or build on, their beach in a pan. Pass out popsicle
sticks, small blocks of wood and other objects to represent structures. Where will they place the structures? Why? How can they protect the structures from erosion and waves? Have students create waves. What happens? Where are the structures the most stable?
3. Lead a class discussion with questions such as: Where was the best place to build on their coastlines? What sediment size seemed to be the most stable? What strategies did students use to protect their structures from erosion? Which were the most effective? What are pros and cons of people building on coastlines?

## Discussion:

Now that students have built a beach in a pan, have them revisit the original focus question: How do waves shape beaches? Students may think on their own or discuss with a partner. Then in their science notebook, you may have them draw a line of learning and under it add to their original thoughts about the question.

## Ocean Literacy Principles:

Ocean literacy is an understanding of the ocean's influence on us, and our impact on the ocean. There are seven Ocean Literacy Essential Principles that all people of our blue planet should have an opportunity to learn and understand. This activity touches upon the following Essential Principles:

1. The Earth has one big ocean with many features
2. The ocean and life in the ocean shape the features of Earth
3. The ocean and humans are inextricably interconnected

## Further Your Impact with Sailors for the Sea Powered by Oceana:

As sailors and water-lovers, you are among the first to notice changes to our seas such as fewer marine animals, more pollution and damaged marine habitat. Through our Green Boating initiative, Sailors for the Sea Powered by Oceana provides opportunities for you and your community to address pressing ocean health issues. As a Green Boater, you will be provided with the information, resources and access to combat marine plastic pollution, prevent habitat destruction, source responsible seafood and protect marine animals. From demanding plastic-free alternatives to choosing sustainable seafood, your voice and actions are an important part of restoring the abundance of our oceans and protecting marine habitats. Join our growing Green Boating Community today.

## Sand Grain Sizes

Name:

Sand is always in motion. Beaches are always changing.
How do waves and wind affect sand grain size on a beach?

## PREDICT

- Sequence the sand samples in the boxes below.

- I think the sand grain sizes on a beach are influenced by:
- Explain your thinking.

## EXPLORE

Build a beach in a pan.

1. Cover the shallow end of your paint pan with sand grains of different sizes.
2. Slowly pour water into the deep end of the pan.
3. Use your wave maker and practice making waves in the pan. Try to make waves of the same height and frequency.
4. Reshape the sand to what it was when you began making waves. SLOWLY make waves that sweep up onto the sand. Keep making waves until over half of the sand is washed from the sand pile and extends down the slope toward the deep end of the pan.

Answer these questions:

- What caused the sediment to move?
- What caused the sediment to stop moving?
- Change the size and frequency of your waves. How does that affect the distribution of sediments?
- Was your prediction correct? Why or why not?

## Beach in a Pan Investigation

Name:

What causes beaches to have different shapes?
Reshape your beach in a pan to the original setup.
Choose one of the variables listed below. Follow the instructions for how to change your beach. Create waves and record your data below.

QUESTION

- How does $\qquad$ affect beach shape?
(Write in one variable.)

## PREDICTION

- I predict the shape of the beach will $\qquad$
(change, stay the same, lose sand, so on)
because $\qquad$ .
- Illustrate the profile of your beach.

## PROCEDURE

- I changed this variable: $\qquad$
(beach slope, wave angle, wave size or wave frequency)
- I kept these variables the same: $\qquad$
(amount of water, amount of sand, etc.)
- Now illustrate the profile of your beach.

Choose one to investigate!

Experimental Variables

## Beach Slope (angle)

How do you think the slope of the beach affects its shape?

Put a book or block of wood under the sand end of the pan to increase the slope.

Wave Size and/or Frequency
How do large waves affect the shape of the beach? Small waves? Fast waves? Slow waves?

Move the wave maker slower or faster and with more and less force to change the waves.

## Wave Angle

What happens if the waves come from a right (90 degree) angle? What if they come from an acute angle such as 60 degrees or 45 degrees)?

Change the orientation of the wave maker in the water to change the angle of the waves to the beach.

## CONCLUSION

- My prediction was

SUPPORTED NOT SUPPORTED because:
(Circle one.)
